

TRENCH BREAKER SPACING

NOTES:

1. Depending on site specific conditions of slopes exceeding 40%, the spacing between trench breakers may continue diminishing as illustrated, or may cease diminishing once a spacing of 30 to 35 feet has been reached.
2. The preferred construction material for trench breakers is sand bags, which are durable yet flexible and will conform to gradual shifting of pipeline and backfill, while serving their function: impede the flow of subsurface water along the trench.
3. In agricultural lands, top of trench breaker will not be closer than two feet from the restored surface.
